Assessing country-level efforts to link research to action

John N Lavis, Jonathan Lomas, Maimunah Hamid, & Nelson K Sewankambo

Abstract We developed a framework for assessing country-level efforts to link research to action. The framework has four elements. The first element assesses the general climate (how those who fund research, universities, researchers and users of research support or place value on efforts to link research to action). The second element addresses the production of research (how priority setting ensures that users’ needs are identified and how scoping reviews, systematic reviews and single studies are undertaken to address these needs). The third element addresses the mix of four clusters of activities used to link research to action. These include push efforts (how strategies are used to support action based on the messages arising from research), efforts to facilitate “user pull” (how “one-stop shopping” is provided for optimally packaged high-quality reviews either alone or as part of a national electronic library for health, how these reviews are profiled during “teachable moments” such as intense media coverage, and how rapid-response units meet users’ needs for the best research), “user pull” efforts undertaken by those who use research (how users assess their capacity to use research and how structures and processes are changed to support the use of research) and exchange efforts (how meaningful partnerships between researchers and users help them to jointly ask and answer relevant questions). The fourth element addresses approaches to evaluation (how support is provided for rigorous evaluations of efforts to link research to action).

Introduction

The idea of linking research to action in the health sector has captured a great deal of international attention. In late 2004 WHO issued the World report on knowledge for better health, with a chapter devoted to linking research to action. Shortly thereafter WHO convened the Ministerial Summit on Health Research in Mexico City, and the resulting Mexico statement on health research called on “all major stakeholders to strengthen or to establish activities to communicate, improve access to, and promote the use of reliable, relevant, unbiased and timely health information.” In May 2005 the World Health Assembly called on WHO Member States to “establish or strengthen mechanisms to transfer knowledge in support of evidence-based public health and healthcare delivery systems, and evidence-based health-related policies”; it also called on WHO’s Director-General to “assist in the development of more effective mechanisms to bridge the divide between ways in which knowledge is generated and ways in which it is used, including the transformation of health-research findings into policy and practice.”

But statements and resolutions are easier made than acted on. Those who want to take meaningful steps to link research to action would ideally be able to draw on high quality, locally applicable research to inform their efforts. Those interested in linking research to action in clinical environments can draw on an overview of systematic reviews of randomized trials of interventions designed to better align health-care professionals’ practice with research as well as a systematic review of randomized controlled trials of strategies for guideline dissemination and implementation. Most of the studies included in these reviews were conducted in high-income countries. However, these interventions should also be evaluated in low- and middle-income countries. Those interested in linking research to action in the areas of health management and policy-making have to deduce the attributes of potential interventions from systematic reviews of observational studies that examine the factors that influence the use of research. For example, interactions between researchers and health-care policy-makers and the timing or timeliness of research being made available appear to increase the likelihood that research will be used by policy-makers. Hence, interventions such as interactive workshops that bring together researchers and health-care policy-makers and web sites that provide “one-stop shopping” for systematic reviews have been promoted (but not yet evaluated).

Health-care professionals, managers and policy-makers are not the only people who may use research. The full range of potential users (outside the research community itself) includes the general public, patients, health-care professionals, health managers, executives of biomedical companies and public policy-makers. While being someone who uses research may be a small role for members of these groups, we use the term “research user” throughout as shorthand for these groups.) Some intermediary groups — by which we mean the media, civil society groups, professional associations and other groups that work at the interface between researchers and users of research — may also have critically
important roles in linking research to action.

In this paper we develop a framework for assessing country-level efforts to link research to action. The main purpose of the framework is to inform country-level dialogues about the domains to which attention could be directed in order to link research to action. Countries provide a natural unit for assessment given that there may be a division of labour within a country (for example, among research funders). A country’s capacities and constraints will affect the initial focus of their efforts (for example, creating a demand for research may be one of the first steps for some countries whereas integrating and building on existing efforts may be among the first steps for others). Capacities will also affect a country’s requirements for partnerships beyond its borders (for example, regional initiatives may provide economies of scale and global initiatives may provide support). When discussing efforts to link research to action within a country, the term “action” includes maintaining the status quo, which can sometimes take as much effort or more than bringing about change. The framework does not include action in the form of commercialization, however, because the different context brought about by the profit motive warrants separate treatment.

Given the state of the research in this field, many elements of the framework are based only indirectly on research. If countries select and implement one or more options from the framework among particular groups and evaluate them rigorously then 5–10 years from now we should be in a much better position to refine the framework and ensure that its elements are solidly supported by research. Had such evaluations been undertaken for the frameworks that have already been developed for policymakers, we would have a more rigorous research base from which to draw now. The main purpose of the examples offered here is to highlight how the framework is grounded in promising innovations that are being implemented for one or more user groups. These innovations warrant wider consideration and rigorous evaluation.

Key concepts
Talk of linking research to action often puts fear into those who prefer research to be focused on discovery rather than application. But these two goals need not be in conflict. Discoveries made today are essential to the applications of tomorrow, and making efforts to forge better links between discovery and application is essential to reaping the benefits of investment in discovery. Many researchers develop innovations in basic science, theory and methodology. Researchers draw on these innovations to conduct studies and write articles and reports. And then later, researchers draw on individual contributions to produce systematic reviews. A fraction of these systematic reviews (and, occasionally, single studies) will yield actionable messages for one or more categories of potential research users; at other times the reviews will yield calls for more or different types of research. Talk of linking research to action is then, in part, simply talk about focusing our efforts to link research to action at the apex of the knowledge pyramid while continuing to build a solid base for the pyramid (Fig. 1). Discovery and application are independent points along a continuum; they are not competing objectives for the role of research in society.

The funders and producers of discovery-oriented research, who function in an environment where others have taken the lead on linking research to action outside the research community, can presumably remain focused on discovery and, when appropriate, on linking research to action by researchers. These researchers will then be better positioned to explore applications of basic science or create derivative theoretical and methodological innovations. The funders and producers of discovery-oriented research, who function in an environment where others have not taken the lead on linking research to action, face a greater challenge. Those who disburse public funds to these funders and researchers may well ask them why at least some of the disbursements are not allocated to linking research to action outside the research community.

Systematic reviews
For those interested in applying research, the challenge is different: there is a need to collectively create music, not noise, for the select ears of research users. Faced with a desire to link research to action, the first impulse of many funders and researchers is to confuse marketing with targeted assistance by promoting all research, regardless of its contribution to the global pool of knowledge. But funders and researchers who market single studies, articles and reports can do harm. Take, for example, the issue of whether to allow private for-profit hospitals to compete with private not-for-profit hospitals. A systematic review of studies comparing mortality rates in private for-profit hospitals with those in private not-for-profit hospitals found 15 studies that met the eligibility criteria; all but one study found a survival advantage for being treated in not-for-profit hospitals. Funders and researchers who promoted the introduction of for-profit hospitals on the basis of the single study with a different result were potentially doing harm.

For potential research users, systematic reviews offer four advantages over single studies; the first two advantages apply primarily to meta-analyses that address the question “what works?” First, the likelihood of being misled by research is lower with a systematic review than with an individual study (that is, bias is reduced). Second, confidence in what can be expected from an intervention is higher with a systematic review than with an individual study (that is, precision is increased). Third, drawing on an existing systematic review constitutes a more efficient use of time because the research literature has already been identified, selected, appraised and synthesized in a systematic and transparent way; potential research users can thus focus on assessing the local applicability of a review and on collecting and synthesizing other types of information, such as routine health information. Fourth, a systematic review can be more constructively contested than an individual study because debate will focus on appraisal and synthesis rather than on why one study was identified and selected over others.

Systematic review methodologies increasingly lend themselves to providing responses to the many different types of questions asked by different potential research users. For example, health managers and policy-makers are interested in finding the most effective solutions to the most burdensome health problems, the most effective ways to fit these solutions into complex health systems (or the most effective ways to organize health systems) and the most effective ways to bring about desired changes in health systems. But in addition to asking questions about effectiveness (does changing X change Y?), they also ask questions about cost effectiveness (is X1 more cost effective than X2 in achieving
a one-unit change in Y?), relationships (is X associated with Y?), mechanisms (how are X and Y linked or why does changing X change Y?), and meaning (how have individuals viewed or experienced X or Y?). A variety of new approaches have been developed to conduct and update syntheses of research to address this broad array of questions.20–23 Although not all developers or users of these new approaches agree with labelling them systematic reviews, for convenience we use that label here as a generic term for all these forms. However, there remain legitimate and important differences in perspectives about a number of these approaches and these warrant further debate.24,25

**Approaches to link research to action**

While actionable messages arising from systematic reviews may be the natural unit of research to consider when attempting to link research to action, people are still needed to make these links. Four approaches can be employed, either singly or in combination, to link research to action (Fig. 2).1,26 “Push” efforts are led by researchers, intermediary groups and other purveyors of research (such as communications staff).27 Such efforts are well suited to situations where the potential research users are unaware that they should be considering a particular message (or in some cases would prefer to continue to disregard it). “User-pull” efforts involve patients, health-care professionals, civil servants and others “reaching in” to the research world to extract information for a decision that they face.28 Researchers and intermediary groups can facilitate these efforts by improving access to optimally packaged research that is of high quality and relevance. User-pull efforts are well suited to situations where potential users have identified an information gap and want to address the gap in a timely way. Exchange (or “linkage and exchange”) efforts occur when the producers or purveyors of research develop a partnership with a group who uses research.29 Such partnerships are well suited to situations where the two groups can establish a shared understanding about the questions to ask, how to answer them through a systematic review or as part of a research project or programme, and how to weight the research and other types of information that each group brings to the table.

A fourth approach, which integrates efforts through large-scale knowledge translation platforms, includes elements of the push, pull and exchange approaches. For example, a proposal for the Regional East African Community Health (REACH)-Policy initiative includes:

- a governing board comprising representatives from groups of producers, purveyors and users (that is, an exchange approach);
- a clear goal (that is, improving people’s health and health equity in east Africa through the more effective use and application of knowledge to strengthen health policy and practice);
- regular priority-setting processes to ensure that systematic reviews and efforts to link research to action are highly relevant to the needs of potential research users;
- push efforts in areas where actionable messages have been identified; and
- a range of efforts to facilitate user pull (such as one-stop shopping for optimally packaged systematic reviews of high quality and relevance, and a rapid-response unit that provides written summaries, telephone consultations or in-person consultations about the best research in a timely way).

There is more than one approach to linking research to action, and not every approach will work in all situations. For example, a health-care professional with a patient in her office or a senior civil servant who has to brief the health minister in 5 minutes cannot wait for a push effort or a partnership. Similarly, the five researchers who study a particular issue in a country cannot respond to all phone
calls from, or develop partnerships with, every clinic or hospital. A community health centre that wants to undertake community-based research to inform its strategic direction while developing local capacity to produce and use research may not be well served by research from other communities that have similar socioeconomic and ethnocultural profiles. Moreover, a single knowledge-translation platform will still leave many actionable messages unused and many user groups without service. Given the failings of any one approach operating in isolation, there is great value in using all four approaches simultaneously.

Framework for assessing country-level efforts

The proposed framework has four elements for assessing country-level efforts to link research to action: the general climate for research use, the production of research that is both highly relevant and appropriately synthesized for research users, the mix of clusters of activities used to link research to action, and the evaluation of efforts to link research to action (Table 1). When discussing the mix of activity clusters, elements of the integrated approach are discussed in the context of the other three approaches. Additionally, the user-pull approach is separated into those activities that can be undertaken by the producers or purveyors of research (for example, efforts to facilitate pull by appropriately packaging key messages of the research) and those activities that can be undertaken only by research users (for example, revising decision-making processes to include explicit consideration of research).

In the first element of the framework we posit that the general climate is conducive to linking research to action when the following conditions are met:

• at least some funders have a mandate to support efforts to link research to action and they support these efforts in several ways;
• universities and other research institutions consider such efforts to be in their tenure and promotion processes and work to remove disincentives to link research to action;
• some researchers place value both on promoting the use of research and — if they are to establish mutually respectful partnerships with research users — on the other types of information on which research users regularly draw (for example, public policy-makers draw on legal evidence about institutional constraints, civil servants’ assessments of stakeholders’ interests and public opinion polls); and
• intermediary groups and research users place value on the use of research.

The funding environment poses particular challenges in many low- and middle-income countries because funding may come not only from national bodies but also from international development aid, research institutes in high-income countries or international foundations and agencies, all of which may have broad development, health or international goals rather than nationally focused health research goals.

The second element of the framework focuses on the production of research. We posit that the research enterprise is conducive to linking research to action when the following conditions are met:

• some funders periodically engage potential research users in priority-setting processes, commission or fund scoping reviews to fill information gaps in areas identified as priorities by users, support the production and regular updating of systematic reviews and, when appropriate, fund single studies;
• funders and ethics review boards place value on systematic reviews to justify additional research on a topic; and
• some researchers participate in continuing education programmes to develop their capacity to conduct systematic reviews and respond to the calls for research in priority areas as well as committing to updating regularly systematic reviews they are funded to produce.

The emphasis on production is particularly important in low- and middle-income countries where, apart from a few fields and especially in applied fields, there is a dearth of high quality research that can be linked to action. Our emphasis on “some” funders and researchers, rather than on “all”, is to ensure that gains can be achieved without jeopardizing the innovations in basic science, theory and methodology that form the base of the knowledge pyramid.

The third element in the framework addresses the mix of activity clusters used to link research to action. Push efforts are also likely to be conducive to linking research to action when some funders, researchers or intermediary groups, or some combination of these, engage in the following components of a systematic push effort:

• periodically identify actionable messages arising from systematic reviews (or occasionally from single studies when a strong case can be made for their unique contributions);
• fine-tune messages and related resources for different user group;
• work with and through the most credible messengers for each user group;
• use research-informed strategies to encourage and support action based on the messages; and
• evaluate their impact against achievable objectives.

As emphasized in the Introduction, the degree to which strategies to encourage and support action can be based on research varies by user group. Push efforts are also likely to be conducive to linking research to action when some funders, researchers or intermediary groups, or some combination of these, develop media releases for systematic reviews (rather than only for articles and reports based on single studies) as is now being done by the United States-based Center for the Advancement of Health, when some researchers employ self-assessment tools to evaluate their capacity to develop and execute research-informed push efforts, and when some researchers participate in continuing education programmes to develop these capacities.

We posit that efforts to facilitate user pull are likely to be more conducive to linking research to action when some funders, researchers or intermediary groups, or some combination of these:

• provide one-stop shopping for optimally packaged reviews that are of high quality and relevance (either in stand-alone format as is done through initiatives like the Health Evidence Network of WHO’s Regional Office for Europe and WHO’s Reproductive Health Library or as part of a national electronic library for health as has been done in the United Kingdom);
• profile these reviews during “teachable moments” (for example, as is done for physicians in the United Kingdom through the “Hitting the Headlines” service of the National Library for Health);
### Table 1. Framework for assessing country-level efforts to link research to action

<thead>
<tr>
<th>Domain</th>
<th>Elements</th>
</tr>
</thead>
</table>
| **General climate** | • Some funders have a mandate to support efforts to link research to action as well as to support excellence in research.  
  • Some funders support efforts to link research to action by providing funding for such efforts and by considering such efforts in research-assessment exercises at the level of institutions and (when appropriate) in peer-review processes at the level of research proposals.  
  • Universities and other research institutions support faculty members’ efforts to link research to action by considering such efforts (when appropriate) as part of tenure and promotion processes.  
  • Some researchers place value on promoting the use of research and on recognizing the importance of other types of information on which research users regularly draw to inform their own or their organization’s decision-making.  
  • Intermediary groups (including the media, civil society groups and professional associations) place value on the use of research to inform their target audiences, constituencies or memberships.  
  • Users of research (including funders) place value on the use of research to inform their own or their organizations’ decision-making.  
  • Some researchers and research users (as well as intermediary groups including the media, civil society groups and professional associations) exhibit a commitment to work within a model of ongoing “linkage and exchange” that guides their efforts to produce research and other types of information to link research to action. |
| **Production of research** | • Some research funders periodically engage potential users of research in priority-setting processes to identify priority areas both for research and for efforts to link research to action.  
  • Some funders commission or fund scoping reviews to identify the state of research in priority areas before undertaking efforts to support systematic reviews or additional research on a topic, or both.  
  • Some funders commission or fund the production and regular updating of systematic reviews that address the full range of questions asked by research users in particular priority areas (as well as the documents that assess an intervention, such as health technology assessments, and guidance documents, such as clinical practice guidelines or system-oriented syntheses, that build on these systematic reviews).  
  • Funders and ethics review boards place value on the use of systematic reviews to justify additional research on a topic and on the registration of systematic reviews to avoid unnecessary duplication.  
  • Some researchers respond to funding calls for scoping reviews, systematic reviews and original research (as well as to funding calls for the assessment and guidance documents that build on these systematic reviews) in high-priority areas and commit to regularly update the systematic reviews.  
  • Some researchers periodically participate in skill-development programmes to develop their capacity to conduct systematic reviews (as well as to produce the assessment and guidance documents that build on these systematic reviews) that address one or more of the types of questions asked by potential research users. |
| **Push efforts (as one cluster of activities among a mix of four clusters)** | • Some funders, researchers or intermediary groups, or some combination of these, periodically engage in all or some elements of a systematic push effort by identifying actionable messages arising from systematic reviews (and from single studies when a strong case can be made for their unique contributions), fine-tuning messages and related resources for different user groups, working with and through the most credible messengers for each user group, using research-informed strategies to encourage and support action based on the messages and evaluating their impact against achievable objectives.  
  – For clinicians, research-informed strategies may be drawn from an overview of systematic reviews of randomized trials of interventions designed to better align health-care professionals’ practice with the research, as well as from a systematic review of randomized controlled trials of all guideline dissemination and implementation strategies and a summary of this research from the perspective of low- and middle-income countries.  
  – For public policy-makers, the attributes of potential interventions have to be deduced from systematic reviews of observational studies that examine the factors influencing the use of research in health-care management and policymaking— for example, interventions that encourage interactions between researchers and health-care policymakers that ensure the best available research is made available in a timely way are addressing two factors that increase the likelihood that research will be used by policy-makers.  
  • Some funders, researchers or intermediary groups, or a combination of these, develop media releases for systematic reviews and (when appropriate) profile and place in context locally conducted studies.  
  • Some researchers periodically employ self-assessment tools to evaluate their capacity to develop and execute research-informed push efforts.  
  • Some researchers periodically participate in skill-development programmes to enhance their capacity to develop and execute research-informed push efforts. |
| **Efforts to facilitate user pull (as one cluster of activities among a mix of four clusters)** | • Some funders, researchers or intermediary groups, or a combination of these, maintain user-group specific web sites (or CD-ROMs) that provide one-stop shopping for systematic reviews that are optimally packaged and of high quality and relevance (also, as part of a national electronic library for health, provide access to health statistics, performance indicators and other locally relevant data, as well as names and contact information for people who are familiar with the reviews and data). |
**Domain** | **Elements**
---|---
Efforts to facilitate user pull (as one cluster of activities among a mix of four clusters) | • Some funders, researchers or intermediary groups, or a combination of these, maintain user-group specific web sites that profile systematic reviews that are optimally packaged and of high quality and relevance as well as being locally applicable during “teachable moments”, such as during a period of intense media coverage of an issue
• Some funders, researchers or intermediary groups, or a combination of these, maintain user-group specific rapid-response units that provide written summaries, telephone consultations or in-person consultations about the best available research
• Some funders, researchers or intermediary groups, or a combination of these, periodically participate in skill-development programmes to enhance their capacity to develop and execute efforts to facilitate user pull

User-pull efforts (as one cluster of activities among a mix of four clusters) | • Research users periodically employ user-group specific self-assessment tools to evaluate their capacity to acquire, assess, adapt and apply research
• Research users develop structures and processes to help them to acquire, assess, adapt and apply research; to combine research with other types of information as inputs to decision-making; and to promote the use of research in decision-making
• Research users periodically participate in skill-development programmes to enhance their capacity to acquire, assess, adapt and apply research

Exchange efforts (as one cluster of activities among a mix of four clusters) | • Some trusted individuals (sometimes called “knowledge brokers”) build relationships among researchers and research users who have shared interests
• Some researchers and research users build partnerships around single studies, programmes of research, or systematic reviews to enable them to collectively ask and answer locally relevant questions (for example, to co-produce research and other types of information)
• Some researchers and research users build partnerships around efforts to link research to action, specifically push efforts, to facilitate user pull, and user-pull efforts undertaken by those who use research
• Some researchers and research users develop partnerships outside the context of the co-production of research and efforts to link research to action to enable them to discuss a broad range of issues of mutual interest
• Some researchers and research users periodically participate in skill-development programmes to enhance their capacity to engage in mutually beneficial partnerships

Evaluation | • Some funders provide funding for rigorous evaluations of efforts to link research to action
• Funders, researchers, intermediary groups and user groups participate in rigorous evaluations of efforts to link research to action

- administer rapid-response units of the type described above (as is done for policy-makers through the European Observatory on Health Systems and Policies); and
- participate in programmes to enhance their capacity to develop and execute efforts to facilitate user pull.

Because studies conducted within particular health systems or particular populations in countries may have limited applicability to other health systems or populations, we posit that efforts both to push and to facilitate user pull will need to highlight the factors that influence the local applicability of systematic reviews.19,34

User-pull efforts are likely to be conducive to linking research to action when some research users:

- employ self-assessment tools to evaluate their capacity to acquire, assess, adapt and apply research (such as the tool developed by the Canadian Health Services Research Foundation);28
- develop structures and processes to help them use and promote research (for example, policy-makers may require that submissions make explicit the research and routine health information underlying any assessments of options); and
- participate in skill-development programmes to enhance their capacity to use and promote research (such as the Executive Training for Research Application programme developed by the Canadian Health Services Research Foundation).

Exchange efforts are likely to be more conducive to linking research to action when they are:

- personal and ongoing, thus creating a window onto the research world for the potential research user (beyond the specific study, research programme or systematic review around which the exchange is occurring) and a window onto the health system for the researcher (facilitating an understanding of the cultural and other differences between the contexts of researchers and research users);
- based on a meaningful partnership where the relative roles and expertise of researchers and research users are recognized; and
- supported by skill-development programmes that allow participating researchers and research users to develop their capacity to engage in mutually beneficial partnerships.

These exchange relationships may be developed and nurtured by trusted individuals or organizations acting in the role of what have been called “knowledge brokers”.35 The US-based Agency for Healthcare Research and Quality has paid particular attention to developing partnerships focused on systematic reviews,36 whereas other funders have been more focused on building partnerships around single studies or research programmes.29

For the last element in the framework we posit that evaluations are likely
to support future efforts to link research to action when:
• funding is available for evaluations of large-scale natural or planned innovations to link research to action; and
• funders, researchers, intermediary groups and user groups participate in rigorous evaluations of efforts to link research to action.

Weak evaluation designs that do not examine both the intended and unintended consequences of these innovations will not provide the research needed to inform future efforts to link research to action.

Applying the framework
No country can or should undertake every component of the four elements in the framework, especially in the domains of producing research and facilitating user pull. The production of systematic reviews, for example, is a global responsibility even if their interpretation and translation into actionable messages is best done at the local level. For example, a systematic review conducted in Malaysia may need little adaptation beyond translation before it can be used in deliberative forums and decision-making venues in Thailand. Some forms of facilitating user pull are also a global responsibility. The Cochrane Library, for example, provides one-stop shopping for high quality systematic reviews addressing the question of “what works?” National electronic libraries for health can provide links to this global resource, which can often be accessed for free by individuals in low- and middle-income countries through, for example, the Latin American and Caribbean Center on Health Sciences Information (BIREME), the Health InterNetwork Access to Research Initiative (HINARI), and the International Network for the Availability of Scientific Publications (INASP).

A number of initiatives have attempted to address one or two elements of the framework. For example, the Applied Diarrhoeal Disease Project and the Joint Health Research Systems Project for southern Africa were initiatives that focused primarily on producing highly relevant research and undertaking push efforts. Both emphasized the creation of studies relevant to health policy and systems through the inclusion of policy-makers, managers or health-care professionals in the research-planning process and the dissemination of results, which was achieved through targeting presentations of findings towards those who could act on them.7 The International Clinical Epidemiology Network’s Knowledge “Plus” Program focuses primarily on push efforts involving clinical practice guidelines. The International Health Policy Program focused primarily on exchange efforts by pairing young researchers with policymakers in order to strengthen linkages and inform health policy. The programme relied less on universities than on stand-alone organizations with research capacity.8 As part of its new strategic plan, the Alliance for Health Policy and Systems Research has articulated its intent to focus on all elements of the framework.9

Three regional initiatives that offer great promise are in development. The Regional East African Community Health-Policy initiative proposes to establish a unit located within the East African Health Research Council to address all elements of the framework for Kenya, Uganda and the United Republic of Tanzania. The Western Pacific Region of WHO has launched the planning stages of a project known as Evidence Informed Policy Networks (EVIPNet Asia) to address many elements of the framework for one municipality in China (Beijing), two Chinese provinces (Shandong and Sichuan), the Lao People’s Democratic Republic, Malaysia, and Viet Nam.40 The African Region of WHO has launched a similar programme, known as EVIPNet Africa. The speed with which these regional initiatives are moving suggests they will pioneer new integrated knowledge-translation platforms well before other parts of the world.

Conclusions
The framework for assessing country-level efforts was designed to inform country-level dialogues about the options for linking research to action for different groups of users. Many elements of the framework are based only indirectly on research. To push forward our understanding of these elements and their interrelationships, we should rigorously evaluate innovative country-level efforts targeted at particular user groups. An important first step in any country will be to identify for specific user groups the supportive elements that are already in place (and that warrant evaluation) as well as the unsupportive elements that should be addressed and the as-yet-unassessed elements that should be examined. Initiatives that are under development in sub-Saharan Africa and the western Pacific may provide opportunities to test the framework in a comprehensive way.

Competing interests: none declared.

Résumé
Évaluation à l’échelle d’un pays des efforts pour lier recherche et action
Un cadre permettant d’évaluer à l’échelle d’un pays les efforts pour lier recherche et action a été mis au point. Ce cadre comporte quatre composantes. La première évalue le contexte général (quel appui ou quelle valeur les acteurs qui financent la recherche, les universités, les chercheurs et les utilisateurs des données de recherche accordent-ils aux efforts pour relier recherche et action). La deuxième composante s’intéresse à la production de la recherche (dans quelle mesure la définition des priorités garantit-elle l’identification des besoins des utilisateurs et dans quelle mesure également des analyses de portée, des revues systématiques et des études simples sont-elles entreprises pour répondre à ces besoins). La troisième composante traite de l’utilisation d’une combinaison d’activités relevant de quatre groupes pour établir un lien entre recherche et action. Ces activités comprennent les efforts de type «push» (comment mettre en œuvre des stratégies pour éayer les interventions par des messages en provenance de la recherche), ceux visant à faciliter l’extraction d’informations par les utilisateurs («user pull») [comment s’opère l’approvisionnement à une source unique à partir de revues de haute qualité, présentées de manière optimale, isolément ou dans le cadre d’une librairie électronique nationale en faveur de la santé, comment l’attention est attirée sur ces revues pendant les «fenêtres

تقييم الجهود المبذولة على الصعيد القطري لربط البحوث بالعمل

ابتكرا إطار عمل لتقييم الجهود المبذولة على الصعيد القطري لربط البحوث بالعمل. ويضم إطار العمل أربعة عناصر: يقدم العنصر الأول المناهج العام (كيفية تقديم الدعم من الذين يولون البحوث والجوانب والباحثين والمسببين من البحوث أو كيف تتقدم وغير المقالة). أما العنصر الثاني فيخبر إنه يجب أن تكون المراجعة جيدة دقة، كما أن هناكfulWidgetات إعداد الأولويات أن الحاجات لم تتغير. وتتوفر لتمكين هذه القائمة من القائمة، كجزء من المكتبة الإلكترونية الوطنية للبحوث. كل ذلك يمكن تصنيف هذه المراجعة في لحظات سريعة، ويمكن لوحدها أو كجزء من المكتبة الإلكترونية الوطنية للبحوث، لتمكين هذه القائمة من القائمة.

**Resumen**

Evaluar los esfuerzos realizados en los países para vincular las investigaciones a la acción

Elaboramos un marco para evaluar los esfuerzos desplegados a nivel de país para vincular las investigaciones a la acción. El marco consta de cuatro elementos. El primero evalúa el clima general (de qué manera quienes financian las investigaciones, las universidades, los investigadores y los usuarios de las investigaciones respaldan o valoran los esfuerzos realizados para vincular las investigaciones a la acción). El segundo aborda la producción de investigaciones (cómo mediante el establecimiento de prioridades se asegura que se identifiquen las necesidades de los usuarios, y cómo llevar a cabo revisiones sintéticas, revisiones sistemáticas y estudios independientes para responder a esas necesidades). El tercer elemento aborda la combinación de cuatro tipos de actividades orientadas a vincular las investigaciones a la acción: actividades impulsoras (formas de aplicación de estrategias para apoyar las medidas basadas en los mensajes derivados de las investigaciones), actividades de fomento (de cómo quienes financian las investigaciones, los investigadores y los usuarios les ayudan a dar forma y responder conjuntamente a los interrogantes pertinentes). El cuarto elemento aborda los métodos de evaluación (la prestación de apoyo para la realización de evaluaciones rigurosas de las actividades de vinculación de las investigaciones a la acción).

**Country-level efforts to link research to action**
Country-level efforts to link research to action

29. Lomas J. Using ‘linkage and exchange’ to move research into policy at a Canadian foundation: encouraging partnerships between researchers and policymakers is the goal of a promising new Canadian initiative. Health Aff 2000;19:236-40.
