Dear editor: Acute respiratory distress syndrome (ARDS), represented mainly by the common cold, pharyngitis, nasopharyngitis, pharyngotonsillitis, laryngitis, otitis media, sinusitis, bronchitis, bronchopneumonia, and pneumonia, is the most common reason for seeking medical attention and the fourth cause of mortality in Mexico. The principal agents associated with this syndrome are viral; however, bacterial agents are associated with increased mortality, and the most common microorganisms are Streptococcus pneumoniae, Haemophilus influenzae, Moraxella catarrhalis and Streptococcus pyogenes. In our community there is an increase in failures of common treatments, presumably provoked by an increase in resistant microorganisms or by the presence of uncommon ones.

In order to determine the pathogens most frequently associated with ARDS, their prevalence, and resistance patterns to common antimicrobials, we conducted a clinical survey of 194 students with acute respiratory infection who had not previously received treatment. The students were selected from five high schools belonging to the Universidad Autónoma del Estado de México (UAEM). A clinical diagnosis and appropriate bacteriological culture from the affected sites was conducted for each case.

The clinical distribution of ARDS was: pharyngitis (60.8%), pharyngotonsillitis (34.5%), nasopharyngitis (4.1%) and rhinitis (0.5%). The agents associated with these were: S. pyogenes (23%), M. catarrhalis (55.1%) and S. aureus (49.4%). In addition, no bacterial pathogen could be isolated in 27 of the cultures. A high bacterial resistance to common antimicrobials was found: S. pyogenes showed a resistance pattern to pefloxacin (86.7%) and trimethoprim-sulfamethoxazole (51.1%), whereas the resistance of M. catarrhalis to ampicillin, trimethoprim-sulfamethoxazole, and carbenicillin was higher than 60% and lower than 21% to gentamicin, metilmicin, and nitrofurantoin. The microbial resistance of S. aureus to cefotaxime, ampicillin, penicillin, dicloxaciln, and cefatadime was higher than 80% and lower than 21% for trimethoprim-sulfamethoxazole, gentamicin, cefalotin, and erytromicin. Strains S. pyogenes producing β-lactamase were not found.

ARDS is well recognized as a serious public health problem among specific age groups. Free access to antibiotics and self-medication in most cases, regardless of etiology, have favored an increase in the rate of bacterial resistance in the three most common pathogens: S. pneumoniae, H. influenzae and M. catarrhalis.

It has been suggested that the use of microbiologic tests, such as cultures of the affected sites, can improve diagnostic and therapeutic accuracy and avoid the emergence of resistant strains.

S. pyogenes was the most common pathogen isolated in a single form; however, the identification of M. catarrhalis in all clinical diagnoses, with the exception of nasopharyngitis, was not expected in this population. Currently, it is accepted that M. catarrhalis is the third most common pathogen agent in children and in adults with immunologic compromise or chronic obstructive pulmonary disease. Its role as an etiology agent in healthy adolescents, however, has not been reported. Only a low prevalence rate in carriers of M. catarrhalis has been reported in this age group.

This finding merits some consideration. First, the current rate in carriers of M. catarrhalis must be established in this age group, and specifically, in those who present with ARDS, in order to discard its pathogenic role. Second, even though the rates of colonization were naturally elevated and not associated with disease, M. catharralis is associated with a high beta lactamase production index. This can favor the persistence of strains sensitive to beta lactamic antibiotics through a synergetic effect with non-producing strains (as is the case for S. pyogenes), prolong the clinical course of the disease, and force a change in the selection of the antibiotic in order to avoid the appearance of resistant strains.

The study had some limitations. We were not able to dismiss an etiologic role of M. catarrhalis because all subjects were symptomatic. Although we were not...
able to test the production of the BRO β-lactamase enzyme by *M. catarrhalis*, it was the second pathogen most commonly isolated. We also cannot dismiss the role of those pathogens previously described as commensals in the etiology of ARDS. This needs further investigation. Recently, *S. aureus* has been recognized as an invasive pathogen of the upper tract respiratory and as a responsible of recurrent disease.\(^{17}\) and as a responsible of recurrent disease for drug resistant.\(^{18}\)

The most important fact in this study was the high resistance of *S. pneumoniae* to trimethoprim-sulfamethoxazole, which explains the high degree of failure of antibiotic treatment in our community. Cultures and office visits, despite the costs, should be considered as a strategy before the use of antibiotics.
